

**Abstract**—The purpose of this study was to determine if there were differences in the prevalence of musculoskeletal disorders among different types of workers. Data from the National Longitudinal Study of the Adolescent Health Survey were used to examine self-reported musculoskeletal symptoms among students who reported working during the previous year. The results showed that students who worked in non-manual jobs had higher rates of musculoskeletal symptoms than those who worked in manual jobs. This finding suggests that non-manual work may be more physically demanding than manual work, at least for adolescents.
